(57) **ABSTRACT**

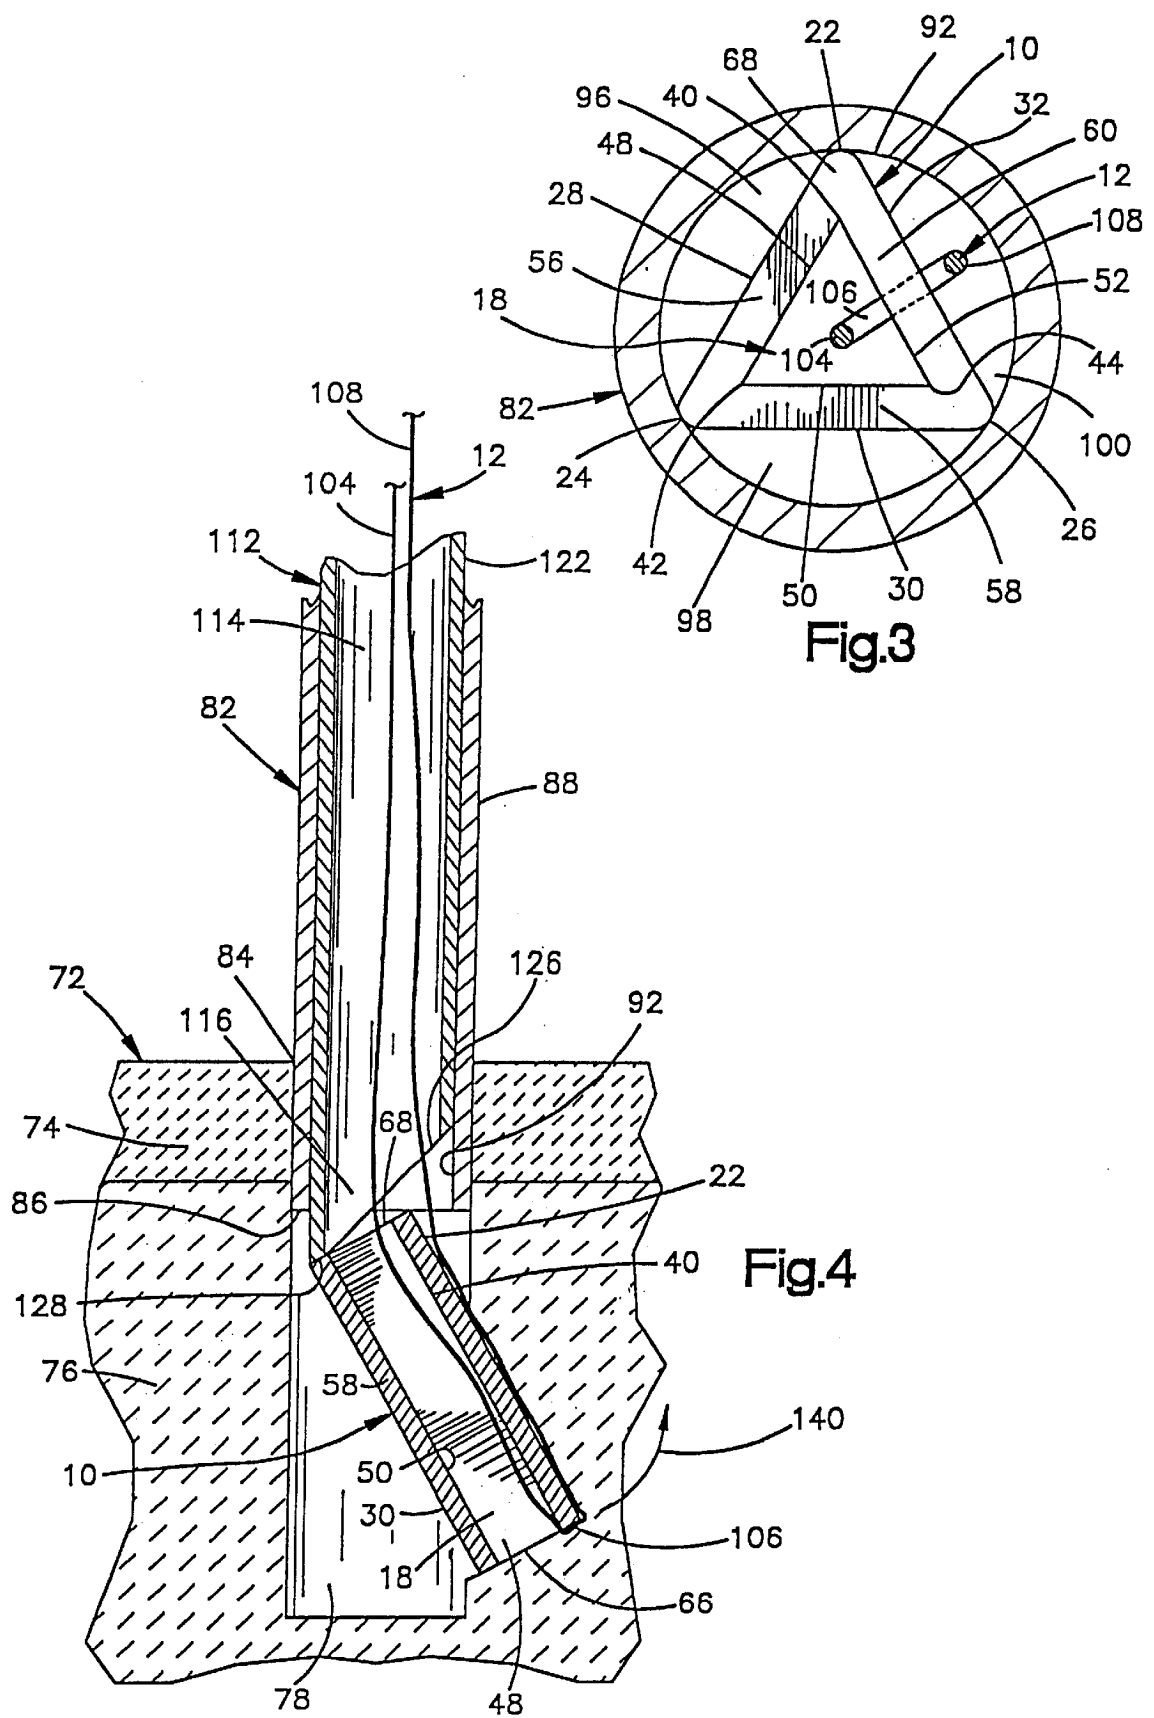

A tubular anchor may have a polygonal cross-sectional configuration with flat outer side surfaces areas connected by a plurality of outer corner portions. A passage through the anchor may be formed by flat inner side surfaces interconnected by inner corner portions. A suture is inserted through the passage. A concentrated force may be applied against a limited area on a trailing end of the anchor to rotate the anchor to move an outer corner portion of the anchor into engagement with body tissue. The suture may engage an inner corner portion of the anchor. The suture may be inserted through a plurality of anchors and the anchors moved through a tubular member into the body tissue under the influence of force transmitted from a trailing anchor to a leading anchor. When the leading anchor is moved into the body tissue, it is rotated under the influence of force applied against a trailing end of the leading anchor. If desired, two anchors may be interconnected. A groove may advantageously be provided among the leading end and side of an anchor to receive the suture.

METHOD AND APPARATUS FOR ANCHORING A SUTURE

RELATED APPLICATIONS

This application is a continuation of U.S. Pat. application Ser. No. 09/569,033, filed May 11, 2000, now U.S. Pat. No. 6,287,325. The aforementioned application Ser. No. 09/569,033 is itself a continuation of U.S. patent application Ser. No. 09/360,721, filed Jul. 26, 1999 and issued as U.S. Pat. No. 6,077,292. The aforementioned application Ser. No. 09/360,721 is a continuation of U.S. patent application Ser. No. 08/929,168, filed Sep. 12, 1997, issued as U.S. Pat. No. 5,941,900. The aforementioned application Ser. No. 08/929,168 is itself a continuation of U.S. patent application Ser. No. 08/667,549 filed Jun. 21, 1996 and issued as U.S. Pat. No. 5,733,306. The aforementioned application Ser. No. 08/667,549 is itself a divisional of co-pending U.S. Pat. application Ser. No. 08/452,310 filed May 26, 1995 and issued as U.S. Pat. No. 5,584,862 on Dec. 17, 1996. The aforementioned application Ser. No. 08/452,310 is itself a divisional of co-pending U.S. patent application Ser. No. 08/291,970 filed Aug. 17, 1994 and issued as U.S. Pat. No. 5,549,630. The aforementioned application Ser. No. 08/291,970 is itself a continuation-in-part of U.S. Pat. application Ser. No. 08/062,295 filed May 14, 1993 and issued as U.S. Pat. No. 5,403,348. The benefit of the aforementioned applications is hereby claimed.

BACKGROUND OF THE INVENTION

The present invention relates to a new and improved anchor and to a new and improved method of using one or more anchors to secure a suture in body tissue.

A known anchor and method of securing a suture in body tissue is disclosed in U.S. Pat. No. 5,041,129 issued Aug. 20, 1991. This patent discloses the use of a hollow outer needle or tube in which an anchor and pusher tube are received. A suture extends through the pusher tube and anchor. Force is applied against a trailing end of the anchor by the pusher tube to move the anchor through the hollow outer needle or tube into body tissue. Other known anchors for use in securing a suture in body tissue are disclosed in U.S. Pat. No. 5,176,682 issued Jan. 5, 1993, U.S. Pat. No. 4,968,315 issued Nov. 6, 1990 and U.S. Pat. No. 4,741,330 issued May 3, 1988.

SUMMARY OF THE INVENTION

An improved suture anchor has a polygonal cross-sectional configuration with an outer side which is formed by a plurality of flat side surface areas which are interconnected by outer corner portions. The anchor has a passage formed by a plurality of flat inner side surface areas which are interconnected by a plurality of inner corner portions. A suture is engageable with one of the inner corner portions to urge an outer corner portion of the anchor into engagement with body tissue. A groove may be provided in the end and/or outer side of the anchor to receive the suture.

A plurality of anchors having the configuration of the improved anchor described above or a different configuration may be used to anchor a suture. When a plurality of anchors are used, the suture is inserted through each of the anchors and the anchors are sequentially moved into the body tissue. As a leading anchor is moved into the body tissue, the suture is tensioned to move a corner portion on the leading anchor into engagement with the body tissue. A connector may be provided between each anchor.

2

BRIEF DESCRIPTION OF THE DRAWINGS

The foregoing and other features of the invention will become more apparent upon a consideration of the following description taken in connection with the accompanying drawings, wherein:

FIG. 1 is a fragmentary pictorial illustration depicting the relationship between an anchor constructed in accordance with one of the features of the present invention and a suture;

FIG. 2 is a fragmentary sectional view, illustrating a method in accordance with another feature of the invention and by which the anchor of FIG. 1 is moved into body tissue;

FIG. 3 is an enlarged sectional view, taken generally along the line 3—3 of FIG. 2, illustrating the relationship of the anchor to a tubular guide member and to a suture;

FIG. 4 is a fragmentary sectional view, taken along the line 4—4 of FIG. 2, illustrating the manner in which force is concentrated against a trailing end portion of the anchor by a pusher member to promote rotational movement of the anchor relative to body tissue;

FIG. 5 is a fragmentary sectional view, generally similar to FIG. 4, illustrating the manner in which the suture is tensioned to urge a corner portion of the anchor into engagement with body tissue;

FIG. 6 is a fragmentary sectional view taken generally along the line 6—6 of FIG. 5, further illustrating the relationship between the corner portion of the anchor, the body tissue and the tubular guide member;

FIG. 7 is a schematicized fragmentary pictorial view illustrating the relationship of the anchor of FIG. 1 to an embodiment of the tubular guide member having a locating surface which positions the anchor in a desired orientation relative to the tubular guide member;

FIG. 8 is a fragmentary cross-sectional view illustrating the construction of a pusher member used with the tubular guide member of FIG. 7;

FIG. 9 is an end view, taken generally along the line 9—9 of FIG. 8, further illustrating the construction of the pusher member;

FIG. 10 is a schematicized cross-sectional view, illustrating the relationship of the anchor to the tubular guide member of FIG. 7 as the anchor moves out of the tubular guide member into body tissue;

FIG. 11 is a side elevational view of an embodiment of the anchor of FIG. 1 having a groove to receive the suture;

FIG. 12 is an end view, taken generally along the line 12—12 of FIG. 11, further illustrating the construction of the groove and the relationship of the suture to the groove;

FIG. 13 is a fragmentary sectional view, generally similar to FIG. 2, illustrating the manner in which a suture extends through a plurality of anchors and the plurality of anchors are moved through a tubular member into body tissue;

FIG. 14 is a fragmentary sectional view, generally similar to FIG. 13, illustrating the manner in which a leading anchor of the plurality of anchors is rotated relative to a trailing anchor as the leading anchor moves out of the tubular member;

FIG. 15 is a fragmentary sectional view, generally similar to FIG. 14, illustrating the manner in which the trailing anchor moves out of the tubular member;

FIG. 16 is a fragmentary sectional view, generally similar to FIG. 15, illustrating the manner in which the leading and trailing anchors are urged into engagement with body tissue by tensioning of the suture;

FIG. 17 is a fragmentary sectional view, generally similar to FIG. 13, illustrating the manner in which a plurality of

anchors cooperate with a tubular guide member having the same construction as the tubular guide member of FIG. 7;

FIG. 18 is an enlarged sectional view, generally similar to FIG. 3, illustrating the manner in which an anchor engages longitudinally extending grooves inside a tubular guide member;

FIG. 19 is an enlarged sectional view illustrating the relationship between a pair of anchors which are interconnected by a connector section; and

FIG. 20 is a schematicized illustration depicting the manner in which the connector section is resiliently deformed by tensioning the suture to urge the anchors into engagement with body tissue in a manner similar to that illustrated in FIG. 16.

DESCRIPTION OF SPECIFIC PREFERRED EMBODIMENTS OF THE INVENTION

Anchor

An anchor 10 (FIG. 1) constructed in accordance with one of the features of the present invention may be used to secure a suture 12 in hard or soft body tissue. The anchor 10 has a tubular wall 13 with an outer side 14 and an inner side 16. The inner side 16 defines a passage 18 which extends through the anchor 10.

The outer side 14 of the tubular wall 13 has a polygonal cross-sectional configuration. Thus, the outer side 14 of the anchor 10 includes a plurality of longitudinally extending outer corner portions 22, 24, and 26. The outer corner portions 22, 24 and 26 are linear and interconnect a plurality of flat rectangular outer side surface areas 28, 30, and 32.

In the specific preferred embodiment of the anchor 10 illustrated in FIG. 1, the tubular wall 13 has an equilateral triangular cross-sectional configuration and forms a hollow prism. Therefore, the angles between the outer side surface areas 28, 30 and 32 at each of the corner portions 22, 24 and 26 is the same, that is, an angle of 120°. It should be understood that the outer side 14 of the anchor 10 could have a different configuration if desired.

For example, the outer side 14 of the anchor 10 could have a cross-sectional configuration corresponding to the configuration of a segment of a circle. An anchor 10 with an outside surface with such a configuration would have a pair of flat rectangular outer side surface areas. These surface areas would be interconnected by a corner portion. An arcuate surface area would extend between the flat outer side surface areas at a location opposite from the corner portion.

The inner side 16 of the anchor 10 has a polygonal cross-sectional configuration which corresponds to and is aligned with the polygonal outer side 14 of the anchor. The inner side 16 of the anchor 10 defines open ends of the passage 18 which extends through the anchor. Thus, the inner side 16 of the anchor has longitudinally extending inner corner portions 40, 42, and 44. The inner corner portions 40, 42 and 44 are linear and are aligned with and extend parallel to the outer corner portions 22, 24, and 26 and to a longitudinal central axis of the anchor 10.

In addition, the inner side 16 of the anchor 10 includes flat rectangular inner side surface areas 48, 50, and 52 which are interconnected by the inner corner portions 40, 42 and 44. The inner side surface areas 48, 50 and 52 extend parallel to and are spaced equal distances from the outer side surface areas 28, 30 and 32. The inner side 16 has a triangular cross-sectional configuration and is aligned with the outer side 14. Thus, the inner side 16 has a longitudinal central axis which is coincident with a longitudinal central axis of the outer side 14.

It is contemplated that the inner side 16 and outer side 14 could have different configurations. For example, the inner

side 16 could be formed with a cross-sectional configuration which corresponds to the configuration of a circle or a segment of a circle. If desired, the inner side 16 could be formed as an almost complete cylinder with a radially extending corner portion which has a circumferential extent of, for example, 40° of the inner side.

In the embodiment of the anchor 10 illustrated in FIG. 1, the tubular wall 13 has three side walls 56, 58 and 60 which are of the same size. The side walls 56, 58 and 60 form rectangular sections of the tubular wall 13. However, it should be understood that the side walls 56, 58 and 60 could have a different configuration and that a greater or lesser number of side walls could be provided if desired.

In one specific embodiment of the anchor 10, the anchor had the configuration illustrated in FIG. 1 and was formed of stainless steel to ASTM designation F-138-86 specification. This specific embodiment of the anchor 10 had a length of 3.10 millimeters. Each of the rectangular side walls 56, 58 and 60 had a width of 1.83 millimeters. The side walls 56, 58 and 60 had a thickness of 0.5 millimeters. The outer corner portions 22, 24 and 26 had a radius of 0.3 millimeters and the inner corner portions 40, 42 and 44 had a radius of 0.15 millimeters.

In another specific embodiment of the invention, the anchor 10 was also formed of stainless steel having an ASTM designation F-138-86 specification. This embodiment of the anchor had a length of 7.2 millimeters. Each of the rectangular side walls 56, 58 and 60 had a width of 1.83 millimeters. The side walls had a thickness of 0.5 millimeters. Both of the specific foregoing examples of the anchor 10 had the hollow prism-shaped configuration illustrated in FIG. 1.

It should be understood that the foregoing specific dimensions and materials for specific examples of the anchor 10 have been set forth herein for purposes of clarity of description. It is contemplated that the anchor 10 could be made with dimensions which are different than the specific dimensions set forth above. However, it is believed that it may be advantageous to make the anchor 10 with a length of from 2 to 8 millimeters and a width of 1.0 to 2.5 millimeters. Of course, the specific dimensions of the anchor 10 can be varied depending upon the environment in which the anchor is to be utilized to secure a suture 12.

In accordance with another of the features of the invention, the anchor 10 is installed in body tissue in an orientation in which one of the outer corner portions 22, 24 or 26 is embedded in body tissue by force applied against an adjacent inner corner portion 40, 42 or 44 by the suture 12. Force applied by the suture 12 against one of the inner corner portions 22, 24 or 26 of the anchor 10 presses the flat outer side surface areas which are interconnected by the embedded corner portion against the body tissue. Thus, if the suture 12 applies force against the inner corner portion 40, the outer corner portion 22 becomes embedded in the body tissue and the flat outer side surface areas 28 and 32 are pressed against the body tissue.

The outer corner portions which are spaced from the embedded outer corner portion 22, 24 or 26 cooperate with the body tissue to stabilize the anchor 10 and hold it against sidewise movement. Parallel flat end surfaces 66 and 68 on the anchor 10 extend perpendicular to the outer side surfaces 28, 30 and 32 and cooperate with the body tissue to retain the anchor against axial movement relative to the body tissue. The cooperation between the outer corner portions 22, 24 and 26 and outer side surfaces 28, 30 and 32 with the body tissue securely retains the anchor 10 in place in the body tissue.

Installation Apparatus

When the anchor **10** is to be installed in human body tissue, the anchor may be pushed directly into the body tissue or into a recess may be formed in the body tissue to receive the anchor. The anchor **10** may be installed in either hard or soft body tissue. In FIGS. **2**, **4**, **5** and **6**, the anchor **10** is to be installed in bone **72** in a human body. The bone **72** includes a compact outer layer **74** and a more porous cancellous tissue **76** which is surrounded by the compact outer layer.

A cylindrical recess or cavity **78** may be formed in the bone tissue to receive the anchor **10** in the manner illustrated in FIG. **2**. It should be understood that the anchor **10** may be used with soft tissue rather than the hard tissue of the bone **72**. It should also be understood that, if desired, the formation of the recess or cavity **78** may be omitted.

A tubular guide member **82** (FIGS. **2-6**) is inserted into the recess **78** (FIG. **2**). Although the tubular guide member **82** could have many different configurations, the illustrated guide member **82** is cylindrical and is inserted through a circular opening **84** to the recess **78**. The guide member **82** is inserted through the compact outer layer **74** of bone tissue. A circular open inner end **86** of the guide member **82** is disposed immediately below (as viewed in FIG. **2**) the inner side of the compact outer layer **74** of bone tissue **72**.

The tubular guide member **82** has a cylindrical outer side surface **88** with a diameter which is substantially the same as the diameter of the cylindrical recess **78** and the circular opening **84** to the recess. Therefore, the bone tissue **82** firmly engages the outer side surface **88** of the guide member **72** to hold the guide member in position relative to the recess **78**. The recess **78** extends inward past the lower (as viewed in FIG. **2**) end **86** of the guide member **82** for a distance which is at least as great as the length of the anchor **10**, that is at least as great as the distance from the end surface **66** to the end surface **68** (FIG. **1**) of the anchor **10**.

The tubular guide member **82** has a cylindrical inner side surface **92** (FIG. **3**). When the anchor **10** is to be installed in the bone tissue **72**, the anchor is positioned in the guide member **82** with the end surface **66** on the anchor leading (FIG. **2**) and the end surface **68** on the anchor **10** trailing. The outer corner portions **22**, **24** and **26** of the anchor **10** are disposed in engagement with the inner side surface **92** (FIG. **3**) of the guide member **82** at equally spaced increments (approximately 120°) about the inner side surface of the guide member. A longitudinal central axis of the anchor **10** is coincident with a longitudinal central axis of the guide member **82**.

The outer side surface areas **28**, **30** and **32** (FIG. **3**) of the anchor **10** are spaced from the inner side surface **92** of the guide member **82**. The outer side surface areas **28**, **30** and **32** extend parallel to a longitudinal central axis of the guide member **82**. The outer side surface areas **28**, **30** and **32** on the anchor **10** cooperate with the inner side surface area **92** on the guide member **82** to form a plurality, of channels **96**, **98** and **100** between the anchor **10** and the inner side surface **92** of the guide member **82**. The channels **96**, **98** and **100** extend axially along the length of the anchor **10**.

A portion **104** (FIG. **2**) of the suture **12** extends downward (as viewed in FIG. **2**) through the upper portion of the guide member **82** into the passage **18** in the anchor **10**. A relatively short portion **106** of the suture **12** extends across the leading end surface **66** of the anchor **10**. A second relatively long portion **108** of the suture **12** extends upward along the outer side surface area **32** of the anchor **10** through the channel **100**. The relatively long portions **104** and **108** of the suture **12** extend from the guide member **82** to a location offset to one side of the recess **78** in the bone tissue **72**.

Once the anchor **10** has been inserted into the tubular guide member **82** in the manner shown in FIGS. **2** and **3**, a hollow cylindrical pusher member **112** (FIG. **2**) is inserted into the guide member **82** through an open upper or outer end of the guide member. The pusher member **112** extends through the open upper or outer end of the guide member **82**. The distance to which the pusher member **112** extends into telescopic engagement with the guide member **82** can be varied by moving the pusher member axially relative to the guide member. Although the pusher member **112** could have a configuration which is different than the cylindrical configuration of the guide member **82**, it is preferred to utilize a pusher member having the same configuration as the guide member.

The suture **12** extends through a cylindrical passage **114** formed in the tubular pusher member **112**. Thus, the portion **104** of the suture **12** extends into the pusher member **112** from a location offset to one side of the recess **78** in the bone tissue **72**. The portion **104** of the suture **12** extends through the passage **114** in the pusher member **112** to the passage **18** in the anchor **10**. The portion **106** of the suture **12** extends across the leading end **66** of the anchor **10**.

The portion **108** of the suture **12** extends upward through the channel **100** along the outer side of the anchor **10** (FIGS. **2** and **3**). The portion **108** of the suture **12** then extends through an open lower or inner end portion **116** (FIG. **2**) of the pusher member **112** into the passage **114** in the tubular pusher member. The portion **108** of the suture **12** then extends from the open upper end of the pusher member to a location which is offset to one side of the recess **78**. A surgeon can manually grip the suture **12** adjacent to an open upper end of the pusher member **112**.

The pusher member **112** has a cylindrical outer side surface **122** which telescopically engages the cylindrical inner side surface **92** of the guide member **82**. The cylindrical outer side surface **122** of the pusher member **112** has a diameter which is just slightly less than the diameter of the cylindrical inner side surface **92** of the guide member **82**. Therefore, the pusher member **112** can slide freely along the inner side surface **92** of the guide member **82** while the guide member holds the inner side surface of the cylindrical pusher member in alignment with the longitudinal central axis of the anchor **10** (FIG. **2**). Thus, the cylindrical inner side surface **92** of the guide member **82** engages the outer corner portions **22**, **24** and **26** of the anchor **10** to guide movement of the anchor and engages the outer cylindrical side surface **122** of the pusher member **112** to guide movement of the pusher member.

The open end portion **116** of the pusher member **112** is axially tapered to enable the pusher member **112** to apply a concentrated force against the trailing end surface **68** (FIG. **2**) of the anchor **10**. Thus, the pusher member **112** has a lower (as viewed in FIG. **2**) end surface **126** which is skewed at an acute angle to a longitudinal central axis of the pusher member (FIG. **4**). In addition, the pusher member **112** has a flat end surface **128** which engages the trailing end surface **68** of the anchor **10**.

The flat end surface **128** has a length and width which enables it to engage the trailing end surface **68** of the anchor regardless of the orientation of the pusher member **112** relative to the trailing end surface **68** of the anchor. This enables the pusher member **112** to engage the trailing end surface **68** of the anchor at a location adjacent to one of the outer corner portions **22**, **24** or **26** (FIG. **2**) of the anchor and/or to engage the anchor at a location adjacent to one of the outer side surface areas **28**, **30** or **32** of the anchor.

The tapered configuration of the open end portion **116** of the pusher member **112** results in the pusher member apply-

ing a concentrated force against the trailing end surface 68 of the anchor at a location which is offset from the central axis of the anchor. Since the force applied by the pusher member 112 to the trailing end surface 68 of the anchor is offset from the central axis of the anchor 10, a torque is applied to the anchor which tends to rotate the anchor about an axis extending through the location where the end portion 116 of the pusher member 112 engages the trailing end surface 68 of the anchor.

When the anchor 10 is in the guide member 82 (FIGS. 2 and 3), the outer corner portions 22, 24 and 26 of the anchor member engage the cylindrical inner side surface 92 of the guide member 82 to retain the anchor against rotational movement under the influence of the concentrated force applied against the trailing end surface 68 of the anchor by the pusher member 112. Thus, the cylindrical inner side surface 92 of the guide member 82 cooperates with the anchor 10 to retain the longitudinal central axis of the anchor 10 coincident with the longitudinal central axis of the guide member. In addition, the cylindrical inner side surface 92 of the guide member 82 cooperates with a cylindrical outer side surface 132 of the pusher member 112 to retain the pusher member in an orientation in which the longitudinal central axis of the pusher member is coincident with the longitudinal central axis of the guide member 82.

In the embodiment of the invention illustrated in FIGS. 2 and 3, the guide member 82 and the pusher member 112 both have cylindrical configurations. However, it is contemplated that the pusher member 112 and guide member 82 could have different configurations. For example, the guide member 82 and the pusher member 112 could both have triangular cross-sectional configurations. If desired, the guide member 82 could have a circular cross-sectional configuration and the pusher member 112 could have a triangular cross-sectional configuration.

Installation Procedures

When the anchor 10 is to be installed in body tissue, which may be either hard or soft tissue, the suture 12 is inserted through the passage 18 (FIG. 2) in the anchor 10. The relatively long portion 104 of the suture 12 extends through the passage 18 to the portion 106 of the suture. The portion 106 of the suture extends across the end surface 66 of the anchor. The portion 108 of the suture extends along the outer side 13 of the anchor 10. In FIG. 2, the portion 108 of the suture 12 extends along the outer side surface area 32. However, the portion 108 of the suture 12 could extend along any one of the outer side surface areas 28, 30 or 32.

Once the suture 12 has been inserted through the passage 18 in the anchor 10, the anchor is inserted into the guide member 82. As this is done, the outer corner portions 22, 24 and 26 (FIG. 3) of the anchor engage the inner side surface 92 of the guide member 82 to position the anchor relative to the guide member. The portion 108 of the suture 12 extends through the channel 100 formed between the outer side surface area 32 on the anchor 10 and the inner side surface 92 of the guide member 82. The guide member 82 retains the anchor 10 in an orientation in which a longitudinal central axis of the anchor is coincident with a longitudinal central axis of the guide member.

Either before or after the anchor 10 is inserted into the guide member 82, the suture 12 is inserted through the open ended passage 114 (FIG. 2) in the pusher member 112. After the anchor 10 has been inserted into the guide member 82, the pusher member 112 is inserted into the guide member. The open leading end portion 116 of the pusher member 112 is moved into engagement with the trailing end surface 68 of the anchor 10.

The pusher member 112 is pressed against the trailing end surface 68 of the anchor 10 to move the anchor through the guide member 82 toward the recess 78 in the bone 72. As this is occurring, the anchor 10 and pusher member 112 may rotate relative to each other and to the guide member 82 about their coincident central axes. However, the inner side surface 92 of the guide member 82 engages the corner portions 22, 24, and 26 of the anchor 10 to retain the anchor against rotational movement about an axis extending transversely to and offset from the longitudinal central axis of the anchor. Thus, the corner portions 22, 24 and 26 on the anchor 10 slide along the inner side surface 92 of the guide member 82 to maintain the longitudinal central axis of the anchor coincident with the longitudinal central axis of the guide member.

A concentrated force is applied against the trailing end surface 68 of the anchor by the tapered end portion 116 of the pusher member 112. The pusher member 112 applies the concentrated force against the anchor 10 at a location which is offset to one side of the longitudinal central axis of the anchor 10. Thus, the flat end surface 128 on the tapered end portion 116 of the pusher member 112 engages the anchor 10 at a trailing end of one of the corner portions 22, 24 or 26 and/or a trailing end of one of the sidewalls 56, 58 or 60. The tapered end portion 116 of the pusher member 112 has a radial thickness which is sufficient to enable the tapered end portion to span one of the channels 96, 98 or 100 (FIG. 3) to engage the trailing end of a sidewall 56, 58 or 60 at a location spaced from the corner portions 22, 24 and 26 of the anchor 10.

Engagement of the tapered end portion 116 of the pusher member 112 with the trailing end of the anchor 10 at a location offset to one side of the longitudinal central axis of the anchor results in the application of torque to the anchor. This torque tends to rotate the anchor about an axis extending through the location where the tapered end portion 116 of the pusher member 112 engages the trailing end surface 68 on the anchor. The outer corner portions 22, 24 and 26 of the anchor 10 engage the inner side surface 92 of the guide member 82 to hold the anchor against rotation under the influence of the torque applied to the anchor by the pusher member 112 as the anchor moves through the guide member.

As the pusher member 112 moves downward (as viewed in FIG. 2) relative to the guide member 82, the anchor 10 is pushed downward in the guide member. As this occurs the anchor 10 pulls the suture downward. Thus, force is transmitted from the leading end surface 66 of the anchor 10 to the portion 106 of the suture 12 to pull the suture into the pusher member 112 and guide member 82.

As the anchor continues to move downward (as viewed in FIG. 2), the leading end of the anchor and the portion 106 of the suture 12 emerge from the open lower end 86 of the guide member 82 into the recess 78. As the anchor 10 moves through the open lower (as viewed in FIG. 2) end portion of the guide member 82, the suture 12 is tensioned to apply force against the leading end surface 66 of the anchor. The surgeon pulls on the portions 104 and 108 of the suture 12 to tension the suture. This force pulls the anchor upward (as viewed in FIG. 2) against the pusher member 112.

As the suture is tensioned and the trailing end portion of the anchor 10 begins to move out of the guide member 82, the suture slides along one of the inner side surface areas 48, 50 or 52 on the anchor into one of the inner corner portions 40, 42 or 44. This tends to rotate the anchor about its longitudinal central axis relative to the pusher member 112 to move one of the side walls 56, 58 or 60 on the anchor into alignment with the tapered end portion 116 of the pusher

member 112. As this occurs, the force applied by the tapered end portion 116 of the pusher member 112 becomes concentrated at the trailing end portion of one of the side walls 56, 58 or 60 of the anchor.

For example, the anchor 10 rotates about its central axis from the position shown in FIG. 2 to the position shown in FIG. 4. When this occurs, the surface 126 on the tapered leading end portion 116 of the pusher member 112 engages the trailing end of the side wall 58 (FIG. 1) of the anchor 10. This results in the force applied by the pusher member 112 being concentrated at a location which is opposite from the outer corner portion 22 of the anchor. By concentrating the force applied against the trailing end surface 68 of the anchor by the pusher member 112 at a location opposite from the corner portion 22, the torque applied to the anchor 10 by the pusher member 112 tends to rotate the anchor in a clockwise direction, as indicated by the arrow 140 in FIG. 4.

Simultaneously with rotation of the anchor 10 about its central axis, the tension in the suture 12 applies force against the leading end surface 66 of the anchor. The force applied against the leading end 66 of the anchor 10 by the suture 12 pulls the trailing end 68 of the anchor back or upward (as viewed in FIG. 4) toward the tapered leading end portion 116 of the pusher member 112. Therefore, the tension in the suture 12 tends to further rotate the anchor 10 in a counterclockwise direction (as viewed in FIG. 4), in the manner indicated schematically by the arrow 140. The inner corner portion 40 of the anchor 10 holds the suture 12 against sidewise movement relative to the anchor and concentrates the force applied by the suture to the anchor at the inner corner portion of the anchor.

Under the combined influence of the concentrated force applied against the trailing end surface 68 of the anchor 10 by the pusher member 112 and the force applied against the inner corner portion 40 of the anchor adjacent to the leading end surface 66 by the suture 12, the anchor is rotated into the cancellous bone tissue 76, in the manner indicated schematically by the arrow 140 in FIG. 4. Thus, the anchor 10 is rotated about an axis which extends perpendicular to and is offset from the central axis of the guide member 82. The axis about which the anchor 10 rotates extends through the location where the leading end surface 128 on the pusher member 112 engages the trailing end surface 68 on the anchor 10. As this occurs, the pusher member 112 continues to move axially downward (as viewed in FIG. 4) in the guide member 82 into the recess 78. The anchor 10 continues to rotate about the axis extending through the location where the end surface 128 on the pusher member 112 engages the end surface 68 on the anchor 10 until the surface 68 on the anchor moves into abutting engagement with the sloping end surface 126 on the pusher member 112.

The combination of concentrated force pushing against the trailing end surface 68 of the anchor on one side of the longitudinal central axis of the anchor and a pulling force applied against the leading end surface 66 at a corner portion of the anchor on the opposite side of the longitudinal central axis of the anchor results in a substantial counterclockwise (as viewed in FIG. 4) torque which causes the anchor to rotate against the resistance provided by the soft cancellous tissue 76 of the bone 72. This results in the anchor 10 moving from the upright orientation shown in FIG. 2 through the orientation shown in FIG. 4 toward an orientation in which the trailing end surface 68 on the anchor 10 engages the sloping end surface 126 on the pusher member 112.

When the trailing end surface 68 on the anchor 10 engages the sloping end surface 126 (FIG. 4) on the pusher member

112, the central axis of the anchor extends perpendicular to the sloping end surface 126 and is skewed at an angle of 45° to the central axis of the guide member 82. The pusher member 112 is then withdrawn into the guide member 82. As the pusher member 112 is moved axially upward as viewed in FIG. 4 into the guide member 82, the force applied by the suture 12 against the leading end 66 of the anchor 10 continues in counterclockwise rotation of the anchor. The force applied against the leading end portion 66 of the anchor by the suture 12 presses the trailing end portion 68 of the anchor against the left (as viewed in FIGS. 4 and 5) side surface of the recess 78.

Continued pulling or tensioning of the suture 12 results in the outer corner portion 22 of the anchor 10 being pulled upward toward the inner or lower (as viewed in FIG. 5) end surface 86 of the guide member 82. As this occurs, the force transmitted from the suture 12 to the anchor 10 pulls the trailing end of the anchor toward the left, as viewed in FIG. 4. Thus, the anchor 10 is first moved toward the right (as viewed in FIG. 4) of the central axis of guide member 82 under the combined influence of force applied against the anchor by the pusher member 112 and the suture 12. The pusher member 112 is then slowly withdrawn and, simultaneously therewith, the anchor 10 is moved toward the right (as viewed in FIGS. 4 and 5) under the influence of force applied against the anchor by tension in the suture 12. The suture 12 is tensioned by the surgeon when he or she manually pulls on the suture.

The force on the anchor 10 causes it to move to the substantially horizontal orientation shown in FIGS. 5 and 6. At this time, the longitudinal central axis of the anchor 10 and the outer corner portions 22, 24 and 26 of the anchor extend perpendicular to the coincident longitudinal central axes of the guide member 82 and pusher member 112. The tension force in the suture 12 pulls the outer corner portion 22 of the anchor 10 upward toward the lower end of the guide member 82.

As this is occurring, the outer corner portion 22 of the anchor 10 becomes embedded in the relatively soft cancellous bone tissue 76 (FIG. 6). In addition, the flat outer side surface areas 28 and 32 press against the cancellous bone tissue to stabilize the anchor 10. The outer corner portions 24 and 26 opposite from the corner portion 22, cooperate with the cancellous bone tissue 76 to further stabilize the anchor and retain the anchor 10 against movement relative to the body tissue 72.

The polygonal configuration of the anchor 10 results in the anchor being retained against movement relative to the body tissue 72. Thus, the outer corner portions 22, 24 and 26 of the anchor 10 become embedded in the body tissue 72. The flat outer side surface areas 28 and 32 of the anchor are pressed against the body tissue to further stabilize the anchor.

With the passage of time, the body tissue tends to grow into the recess 78 and the space caused by moving the anchor 10 from the position shown in FIG. 2 through the position shown in FIG. 4 to the position shown in FIG. 5. As this occurs, the body tissue grows into engagement with the flat outer side surface area 30 of the anchor to further stabilize the anchor. Although the anchor 10 is very stable in the body tissue 72, the anchor can be removed from the body tissue in the same manner as is disclosed in the aforementioned U.S. patent application Ser. No. 08/062,295 filed May 14, 1993 of which this application is a continuation-in-part.

Anchor Guide and Pusher Members—Second Embodiment
In the embodiment of the invention illustrated in FIGS. 1—6, the anchor 10 is randomly oriented relative to the

11

guide member 82. As the anchor 10 emerges from the guide member 82, the force applied against the anchor by tensioning the suture 12 results in the suture moving along an inner side surface area 48, 50 or 52 of the anchor into engagement with one of the inner corner portions 40, 42 and 44. As this occurs, the anchor moves relative to the pusher member 112 to an orientation in which the tapered end portion 116 of the pusher member 112 applies a concentrated force against a portion of the anchor opposite from the inner corner portion engaged by the suture 12. For example, if the suture 12 engages the inner corner portion 40, as shown in FIG. 4, the pusher member 112 applies a concentrated force against the side wall 58 adjacent to the outer corner portions 24 and 26.

It is contemplated that it may be desired to orient the anchor 10 relative to the body tissue 72 before the anchor begins to move into the recess 78. In the embodiment of the invention illustrated in FIGS. 7-10, the tubular guide member is constructed so as to retain the anchor in a selected orientation relative to the guide member as the anchor moves axially through the guide member. In addition, the pusher member is constructed so as to apply a concentrated force against a selected portion of the anchor. Since the embodiment of the invention illustrated in FIGS. 7-10 is generally similar to the embodiment of the invention illustrated in FIGS. 1-6, similar numerals will be utilized to designate similar components, the suffix letter "a" being associated with the numerals of FIGS. 7-10 to avoid confusion.

A tubular guide member 82a (FIG. 7) has a cylindrical outer side surface 88a and a cylindrical inner side surface 92a. In addition, the guide member 82a has a linear locating rib 142 which orients the anchor 10a in the guide member 82a. The locating rib 142 extends axially along the inner side surface 92a of the guide member 82a for the entire length of the guide member. A longitudinal central axis of the locating rib 142 extends parallel to a longitudinal central axis of the guide member 82a.

The locating rib 142 has a flat inwardly facing locating surface 144. The flat locating surface 144 is disposed in a plane which forms a chord to the cylindrical inner side surface 92a of the guide member 82a. The plane in which the locating surface 144 is disposed, extends parallel to the longitudinal central axis of the guide member 82a. The locating surface 144 has an axial extent which is the same as the axial extent of the guide members 82a.

When an anchor 10 is in the orientation shown in FIG. 7, the locating surface 144 engages the flat outer side surface area 30a on the anchor 10a to position the anchor in a predetermined orientation relative to the guide member 82a. The corner portion 22a of the anchor 10a is disposed diametrically across from the locating surface 144. Of course, the anchor 10a could be positioned relative to the tubular guide member 82a with the flat locating surface 144 in abutting engagement with any one of the flat outer side surface areas 28a, 30a or 32a on the anchor.

The corner portions 22a, 24a and 26a (FIG. 7) of the anchor 10a engage the cylindrical inner side surface 92a of the guide member 82a to hold the anchor 10a in alignment with a longitudinal central axis of the guide member 82a. The locating surface 144 engages the flat outer side surface area 30a on the anchor 10a to hold the anchor in a predetermined orientation relative to the longitudinal central axis of the guide member 82a. Thus, the locating surface 144 engages the flat outer side surface 30a on the anchor 10a to prevent rotation of the anchor about its longitudinal central axis relative to the guide member 82a. The longitudinal central axis of the anchor 10a is coincident with the longitudinal central axis of the guide member 82a.

12

The location of the anchor 10a relative to the body tissue into which it is to be inserted can be selected by a surgeon before inserting the anchor. Thus, the outer corner portion 22a of the anchor 10a is diametrically across the guide member 82a from the locating surface 144. At this time, the corner portion 22a of the anchor 10a has a longitudinal central axis which is located in a plane which contains the longitudinal central axis of the locating rib 142. Therefore, by selecting the orientation of the locating rib 142 relative to the body tissue, the surgeon can select the orientation of the outer corner portion 22a of the anchor relative to the body tissue.

When the anchor 10a is installed in body tissue to anchor the suture 12a, in the manner shown in FIGS. 5 and 6 for the anchor 10, the longitudinal central axis of the corner portion 22a of anchor 10a is still disposed in the plane containing the parallel longitudinal central axes of the guide member 82a and the locating rib 142. The longitudinal central axis of the anchor 10a is also disposed in the plane containing the longitudinal central axes of the guide member 82a and the locating rib 142. However, when the anchor 10a is installed in body tissue, in the manner shown in FIGS. 5 and 6 for the anchor 10, the longitudinal central axes of the corner portion 22a and anchor 10a extend perpendicular to the parallel longitudinal central axes of the guide member 82a and locating rib 142.

A pusher member 112a (FIGS. 8 and 9) cooperates with the guide member 82a to apply force against the anchor 10a at locations which are opposite from the outer corner portion 22a and are adjacent to opposite longitudinally extending side surfaces 146 and 148 (FIG. 7) on the locating rib 142. The side surfaces 146 and 148 extend perpendicular to the locating surface 144. The side surfaces 146 and 148 extend parallel to each other and are spaced apart by a distance which is substantially less than the distance between the corner portions 24a and 26a of the anchor 10a.

The pusher member 112a is a cylindrical tubular member having a tapered end portion 116a (FIG. 8). The tubular pusher member 112a has a radially extending slot 150 (FIG. 9) which extends throughout the length of the pusher member and receives the locating rib 142. Opposite side surfaces 151 and 152 of the slot 150 extend parallel to each other and engage opposite side surfaces 146 and 148 on the locating rib 142. Thus, the locating rib 142 cooperates with the slot 150 to orient the pusher member 112a relative to the guide member 82a. Since the anchor 10a is also oriented relative to the guide member 82a by the locating rib 142, the locating rib is effective to orient the pusher member 112a relative to the anchor.

The pusher member 112a has a tapered leading or lower (as viewed in FIG. 8) end surface 128a which applies force against the anchor 10a at locations adjacent to opposite sides of the locating rib 142 in the tubular guide member 82a. The manner in which the end surface 128a on the pusher member 112a applies force against the anchor 10a is indicated schematically in FIG. 7 by the arrows 154 and 156. The arrows 154 and 156 extend parallel to the longitudinal central axis of the locating rib 142 and to the longitudinal central axis of the anchor 10a.

The pusher member force represented by the arrows 154 and 156 is applied against the trailing end surface area 68a on the side wall 58a (FIG. 7) of the anchor 10a opposite from the outer corner portion 22a. Thus, the pusher member 112a applies a force which is concentrated against the same side wall 58a of the anchor as is engaged by the locating surface 144 on the locating rib 142. This results in the pusher member 112a applying force against the trailing end surface

68a of the anchor 10a at locations which are selected by selecting the orientation of the anchor in the guide member 82a.

When the anchor 10a is to be installed in body tissue, the tubular guide member 82a is positioned in a selected orientation relative to the body tissue. Thus, the open lower end 96a (FIG. 10) of the guide member 82a is inserted into a recess in the body tissue, in the manner illustrated in FIG. 2 for the guide member 82, with the locating rib 142 at a location where it is desired to have the outer corner portion 22a of the anchor 10a embedded in the body tissue.

The suture 12a (FIG. 10) is inserted through the central passage 18a in the anchor 10a. Thus, the portion 104a of the suture 12a extends through the passage 18a in the anchor 10a and the portion 108a of the suture 12a extends along the outer side surface 32a of the anchor. The suture is also inserted through the central passage 114a (FIG. 8) in the pusher member 112a.

The anchor 10a is then positioned in the guide member 82a with the flat outer side surface area 30a (FIG. 7) on the anchor in abutting engagement with the flat locating surface 144 on the locating rib 142. The portion 108a of the suture will extend through the channel 100a formed between the inner side surface 92a of the guide member 82a and the outer side of the anchor 10a.

The pusher member 112a is then inserted into the tubular guide member 82a with the portions 104a and 108a of the suture 12a extending through the cylindrical passage 114a in the tubular pusher member. The locating rib 142 extends radially through the slot 150 formed in the pusher member 112a. The side surfaces 151 and 152 of the slot 150 (FIG. 9) engage opposite side surfaces 146 and 148 on the locating rib 142. Engagement of the locating rib 142 with the slot 150 in the pusher member 112a orients the pusher member 112a relative to both the anchor 10a and the guide member 82a.

The lower or leading end surface 128a (FIG. 8) on the pusher member 112a engages the upper end surface of the side wall 58a (FIG. 7) of the anchor 10a adjacent to opposite sides of the locating rib 142. Thus, when the pusher member 112a is pressed against the anchor 10a, the end surface 128a on the pusher member 112a applies force against the trailing end surface 68a of the anchor 10a at the side wall 58a, in the manner indicated by the arrows 154 and 156 in FIG. 7.

The force applied against the trailing end surface 68a of the anchor 10a by the pusher member 112a moves the anchor axially downward (as viewed in FIG. 7) through the guide member 82a until a leading end surface 66a (FIG. 10) on the anchor emerges from the open lower (as viewed in FIG. 10) end 92a of the guide member 82a. During this movement of the anchor 10a through the tubular guide member 82a, both the anchor and the pusher member 112a are maintained in a predetermined orientation relative to the guide member by the locating rib 142. The locating rib 142 cooperates with the pusher member 112a and the anchor 10a to retain them against rotation relative to each other about the central axis of the guide member 82a.

As the anchor 10a begins to emerge from the lower (as viewed in FIG. 10) end portion 86a of the tubular guide member 82a, the force applied against the trailing end surface 68a of the anchor by the pusher member 112a applies a torque to the anchor which tends to rotate the anchor in a counterclockwise direction (as viewed in FIG. 10). As this occurs, the suture 12a is tensioned to apply a force against the inner corner portion 40a of the anchor 10a adjacent to the leading end surface 66a of the anchor. The forces result in the anchor being rotated in a counterclockwise direction as viewed in FIG. 10.

Once the trailing end of the anchor 10a has moved clear of the tubular guide member 82a, the force applied against the leading end surface 66a of the anchor 10a by the portion 106a of the suture 12a moves the anchor 10a toward the left (as viewed in FIG. 10). Therefore, the anchor 10a moves to a position in which it extends diametrically across the open lower end portion 92a of the guide member 82a. This results in the anchor 10a being installed in body tissue in a position similar to that shown for the anchor 10 in FIGS. 5 and 6.

Continued pulling or tensioning of the suture 12a results in the corner portion 22a of the anchor becoming embedded in the body tissue and the outer side surfaces 28a and 32a of the anchor applying force against the body tissue. At this time, the outer corner portions 24a and 26a cooperate with the body tissue to further stabilize the anchor 10a. Once the anchor 10a has been moved into position in the body tissue, both the guide member 82a and the pusher member 112a are withdrawn from the body tissue.

In the embodiment of the invention illustrated in FIGS. 7-10, the locating rib 142 positions the anchor relative to the guide member 82a. However, it is contemplated that many different arrangements of locating surfaces could be provided on the guide member to locate the anchor relative to the guide member. For example, the guide member 82a could be formed with a configuration corresponding to the configuration of a segment of a circle. If this was done, the portion 108a of the suture 12a would be disposed adjacent to the arcuate portion of the guide member while the opposite outer corner portion of the anchor would be engaged by the apex of the guide member. If desired, the guide member could have a polygonal cross-sectional configuration corresponding to the polygonal cross-sectional configuration of the anchor. If this is done, a groove in the guide member could be used as a channel to receive the portion 108a of the suture 12a.

Anchor—Second Embodiment

It is contemplated that during use of the anchor 10 of FIGS. 1-6, it may be desired to protect the suture 12 from engagement with surfaces in the environment in which the anchor is used. In the embodiment of the anchor illustrated in FIGS. 11 and 12, grooves are provided to receive the suture to protect the suture. Since the embodiment of the anchor illustrated in FIGS. 11 and 12 is generally similar to the embodiment of the invention illustrated in FIGS. 1-6, similar numerals will be utilized to designate similar components, the suffix letter "b" being associated with the numerals of FIGS. 11 and 12 to avoid confusion.

An anchor lob has outer corner portions 22b, 24b and 26b which interconnect flat outer side surface areas 28b, 30b and 32b. A central passage 18b extends through the anchor. The anchor 10b has the same configuration as the anchor 10 of FIG. 1.

In accordance with a feature of this embodiment of the invention, the anchor 10b has a groove 162 (FIG. 11) in which the suture 12b is received. The groove 162 has a longitudinally extending main portion 164 which is disposed inwardly from the flat outer side surface 32b of the anchor 10b. The main portion 164 of the groove 162 has a flat bottom surface 166 which extends parallel to the flat outer side surface area 32b and extends between axially opposite ends of the anchor 10b. The main portion 164 of the groove 162 receives the portion 108b of the suture 12b which extends along the outside of the anchor.

The main portion 164 of the groove 162 has a flat longitudinally extending side surface 170 which is disposed in a central portion of the flat outer side surface 32b and a flat longitudinally extending side surface 172 which is

disposed in a central portion of the outer corner portion **22b** (FIG. 12). This enables the portion **108b** (FIG. 11) of the suture **12b** to move from a position adjacent to the central portion of the flat outer side surface **32b** to the outer corner portion **22b** as the inner portion of the suture moves into engagement with the inner corner portion **40b** (FIG. 12) of the anchor **10b**. Thus, as the anchor **10b** is rotated and moved into position relative to the end of the guide member in the manner shown in FIGS. 4 and 5 for the anchor **10**, the portion **108b** of the suture **12b** will move sidewardly, that is in a direction transverse to the longitudinal central axis of the main portion **164** of the groove **162**, into engagement with the longitudinally extending side surface **172** of the groove. This occurs as the portion of the suture which extends through the passage **18b** in the anchor **10b** moves into engagement with the inner corner portion **40b** of the anchor.

In addition, the groove **162** has an end portion **176** which extends transversely to the main portion **164** of the groove **162** and extends across the end surface **66b** of the anchor **10b**. The end portion **176** of the groove **162** extends from a central portion of an end of the side wall **60b** to the inner and outer corner portions **40b** and **22b**. The end portion **176** of the groove **162** receives the portion **106b** of the suture **12b** to protect the suture. Since the end portion **176** of the groove extends from the central portion of the side wall **60b** to the outer corner portion **22b**, the portion **106b** of the suture can move to a location extending between the inner corner portion **40b** and the outer corner portion **22b** as the anchor is moved from the orientation shown in FIG. 4 to the orientation shown in FIG. 5 for the anchor **10**.

Although the groove **162** has been illustrated herein as having both the main portion **164** and the end portion **176**, it is contemplated that the groove **162** could have either just the main portion **164** or the end portion **176** if desired. It is also contemplated that the groove **162** could have a configuration other than the configuration illustrated herein.

Plural Anchors

In the embodiment of the invention illustrated in FIGS. 1-6, a single anchor **10** is used to secure the suture **12** in body tissue. In the embodiment of the invention illustrated in FIGS. 13-16, a plurality of anchors are used to secure a suture in body tissue. Since the embodiment of the invention illustrated in FIGS. 13-16 is generally similar to the embodiment of the invention illustrated in FIGS. 1-6, similar numerals will be utilized to designate similar components, the suffix letter "c" being associated with the numerals of FIGS. 13-16 to avoid confusion.

In accordance with a feature of this embodiment of the invention, a pair of anchors **182** and **184** (FIG. 13) are used to secure a suture **12c** in body tissue. However, a greater number of anchors could be used if desired. The anchors **182** and **184** both have the same general construction as the anchor **10** of FIGS. 1-6. However, the trailing anchor **182** has a tapered leading end portion **186**. If desired, the anchors **182** and **184** could have a construction which is different from the construction of the anchor **10**.

The tapered leading end portion **186** of the trailing anchor **182** extends from an outer corner portion **22c** of the anchor **182** to an outer side surface **30c** on a side wall **58c** and to the corner portions opposite from the corner portion **22c** of the anchor **182**. The outer side surface area **30c** has a flat rectangular configuration. The tapered leading end portion **186** of the anchor **182** includes a flat leading end surface **66c** which is disposed in a plane which is skewed at an acute angle to a trailing end surface **68c**. Other than having the tapered leading end portion **186**, the construction of the anchor **182** is the same as the construction of the anchor **10** of FIGS. 1-6.

The leading anchor **184** has the same construction as the anchor **10** of FIGS. 1-6. Thus, the leading anchor **184** has a leading end surface **66c** which is parallel to the trailing end surface **68c**. The leading and trailing end surfaces **66c** and **68c** of the anchor **184** extend perpendicular to a longitudinal central axis of the suture.

Although it is preferred to use anchors **182** and **184** having the same configuration as the anchor **10** of FIGS. 1-6, the anchors **182** and **184** could have a configuration which is different than the configuration of the anchor **10**. For example, the anchors **182** and **184** could have a cylindrical configuration or any of the other anchor configurations disclosed in the aforementioned U.S. patent application Ser. No. 08/062,295 filed May 14, 1993 of which this application is a continuation-in-part. However, the anchor corresponding to the anchor **182** and having any one of these constructions may be provided with a tapered leading end portion.

Although it is preferred to form the leading anchor **184** with a trailing end surface **68c** which extends perpendicular to the central axis of the anchor, the trailing end portion of the leading anchor **184** could be tapered in a manner similar to the tapered leading end portion **186** of the trailing anchor **182**. If the trailing end portion of the anchor **184** is tapered, the leading end portion of the anchor **182** could extend perpendicular to the central axis of the anchor **182** or could be tapered in a manner similar to that shown in FIG. 13.

When the anchors **182** and **184** are to be used to secure the suture **12c** into bone **72c** or other body tissue, a cylindrical recess **78c** may be formed in the body tissue. A tubular cylindrical guide member **82c** is inserted into the recess **78c** in the manner illustrated in FIG. 13. Although the tubular guide member **82c** has the same construction as the guide member **82** of FIGS. 2-6, a guide member having a different construction could be used if desired.

The suture **12c** is inserted through central passages **18c** in the anchors **182** and **184**. This results in the two anchors **182** and **184** being strung together on the suture **12c**. A portion **104c** (FIG. 13) of the suture **12c** extends through the central passage **18c** in the anchor **182** and through the central passage **18c** in the anchor **184**. A portion **106c** of the suture **12c** extends across the leading end surface **66c** of the leading anchor **184**. A portion **108c** of the suture **12c** extends along the outside of the two anchors **182** and **184**.

After the anchors **182** and **184** have been strung on the suture **12c**, the anchors **182** and **184** are positioned in the tubular guide member **82c**. Corner portions of the anchors **182** and **184** engage a cylindrical inner side surface **92c** of the guide member **82c**. Thus, the corner portions of the anchors **182** and **184** engage the inner side surface **92c** of the guide member **82c** in the same manner as in which the corner portions **22**, **24** and **26** of the anchor **10** engage the inner side surface **92** of the tubular guide member **82** (FIG. 3).

The anchors **182** and **184** are positioned in the cylindrical guide member **82c** with the corner portions of the anchors aligned with each other and with the anchors in a coaxial relationship with each other. The anchors **182** and **184** are also positioned in the guide member **82c** with the anchors in a coaxial relationship with each other and with the guide member. A knife edge end **190** of the tapered leading end portion **186** of the anchor **182** is disposed in engagement with the trailing end surface **68c** of the anchor **184** along the side wall **58c** of the anchor **184**. The knife edge end **190** of the tapered leading end portion **186** of the anchor **182** has a configuration similar to the configuration of a cutting portion of a chisel. The knife edge end **190** extends along the side

wall 58c of the anchor 182 between corner portions at opposite ends of the side wall, that is, between corner portions corresponding to the corner portions 24 and 26 (FIG. 3) of the anchor 10. Thus, force is transmitted from the trailing anchor 182 to the leading anchor 184 along the entire width of the trailing end surface of the side wall 58c of the anchor 184.

A cylindrical tubular pusher member 112c is inserted into the guide member 82c and applies force to the trailing end surface 68c of the trailing anchor 182. The pusher member 112c has a flat circular leading end surface 126c which is disposed in a plane extending perpendicular to a longitudinal central axis of the pusher member 112c. Thus, the pusher member 112c of FIG. 13 does not have a tapered open end portion in the same manner as does the pusher member 112 of FIGS. 2 and 4. However, if desired, the pusher member 112c could be provided with a tapered open end portion having a configuration similar to the configuration of the tapered open end portion 116 of the pusher member 112 (FIGS. 2 and 4).

The circular leading end surface 126c of the pusher member 112c engages the trailing end surface 68c of the trailing anchor 182 at each of the three corner portions of the anchor. This results in the trailing anchor 182 being pushed straight down (as viewed in FIG. 13) by the pusher member 112c. The pusher member 112c does not apply torque to the trailing anchor 182. This is because the force applied to the trailing end surface 68c of the anchor 182 by the pusher member 112c is balanced about the central axis of the anchor.

Although the pusher member 112c does not apply torque to the trailing anchor 182, the trailing anchor 182 is effective to apply torque to the leading anchor 184. This is because force is transmitted from the trailing anchor 182 through the tapered leading end portion 186 of the trailing anchor 182 to the leading anchor 184. The force transmitted from the trailing anchor 182 to the leading anchor 184 is concentrated along the width of the side wall 58c of the leading anchor by the knife edge end 190 of the trailing anchor. This concentrated force is offset from the longitudinal central axis of the leading anchor 184. Therefore, the trailing anchor 182 applies torque to the leading anchor 184 tending to rotate the leading anchor in a counterclockwise direction, as viewed in FIG. 13, about an axis which extends through the location where the knife edge end 190 of the trailing anchor 182 engages the side wall 58c of the leading anchor 184. Thus, the torque applied to the leading anchor 184 by the trailing anchor 182 tends to rotate the leading anchor about an axis which extends parallel to the flat outer side surfaces 30c of the anchors and which extends along a linear line of engagement of the knife edge end 190 of the trailing anchor with the trailing end surface 68c of the leading anchor.

Since the three outer corner portions of the leading anchor 184 are disposed in engagement with the cylindrical inner side surface 92c of the guide member 82c, in the manner illustrated in FIG. 3 for the anchor 10, the leading anchor 184 is restrained against rotational movement under the influence of torque transmitted from the trailing anchor 182 to the leading anchor 184. Thus, the leading anchor 184 is moved straight downward (as viewed in FIG. 13) under the influence of the force transmitted from the trailing anchor 182 to the leading anchor. The leading end surface 66c of the leading anchor 184 applies force against the portion 106c of the suture 12c to pull the suture downward in the guide member 82c.

As the anchors 182 and 184 are moved downward (as viewed in FIG. 13) together along the guide member 82c

under the influence of forces applied against the trailing anchor 182 by the pusher member 112c, the leading anchor 184 moves through the open lower end portion 86c of the guide member 82c. As this occurs, the concentrated force applied against the trailing end surface 68c of the leading anchor 184 by the tapered knife edge end portion 186 of the trailing anchor 182 causes the leading anchor to rotate in a counterclockwise direction, in the manner indicated by the arrow 140c in FIG. 14. This results in the leading anchor 184 rotating about an axis which extends through the location where the knife edge end 190 of the trailing anchor 182 engages the portion of the trailing end surface 68c of the leading anchor 184 disposed on the trailing end of the side wall 58c of the leading anchor 184.

As the leading anchor 184 is being rotated under the influence of the torque applied against it by the trailing anchor 182, the trailing anchor continues to move straight downward (as viewed in FIG. 14) along the tubular guide member 82c. As the leading anchor 184 is rotated in a counterclockwise direction, in the manner indicated by the arrow 140c in FIG. 14, the leading end 66c of the leading anchor moves rightward into the relatively soft cancellous bone tissue 76c. The outer corner portion 22c of the anchor 184 is leading. The wedge-shaped configuration of the outer corner portion 22c of the leading anchor 184 facilitates movement of the leading anchor 184 in the cancellous bone tissue.

As this is occurring, the suture 12 is tensioned by pulling on the two portions 106c and 108c of the suture. This pulls the portion 106c of the suture against the leading end surface 66c of the leading anchor 184. The force applied by the suture 12c to the leading end surface 66c of the leading anchor 184 urges the leading anchor upward and toward the left (as viewed in FIG. 14) toward the tapered leading end portion 186 of the trailing anchor 182. The counterclockwise (as viewed in FIG. 14) rotation of the leading anchor 184 continues until the trailing end surface 68c on the leading anchor engages the leading end surface 66c on the trailing anchor 182.

After the trailing end surface 68c on the leading anchor 184 has engaged the leading end surface 66c on the trailing anchor 182, the pusher member 112c pushes the trailing end surface 68c of the trailing anchor 182 out of the guide member 82c. As this occurs, the outer corner portions of the trailing anchor 182 move out of engagement with the cylindrical inner side surface 92c of the guide member 82c. Force transmitted from the suture 12c through the leading anchor 184 to the trailing anchor 182 causes the trailing anchor to rotate and move leftward toward the position shown in FIG. 15.

As this is occurring, the leading anchor 184 continues to rotate under the influence of the force applied against the leading anchor by the suture 12c. As the suture 12c is tensioned, the two anchors 182 and 184 are rotated together through the position shown in FIG. 15 to the position shown in FIG. 16. When the anchors 182 and 184 reach the position shown in FIG. 16, the outer corner portions 22c of the anchors engage the lower end surface 86 of the guide member 82c and are embedded in the soft cancellous bone tissue.

The force applied against the two anchors 182 and 184 by tensioning the suture 12c presses the leading end surface 66c on the tapered leading end portion 186 of the trailing anchor 182 firmly against the trailing end surface 68c on the anchor 184. At this time, the flat outer major side surfaces on the anchors 182 and 184 press against the soft cancellous bone tissue and the outer corner portions of the anchors 182 and

184 are engaged by the soft cancellous bone tissue to stabilize the anchors 182 and 184 in the same manner as previously explained in conjunction with the embodiment of the invention illustrated in FIGS. 1–6. Therefore, the anchors 182 and 184 are disposed in stable abutting engagement with each other and are held against movement relative to the bone tissue 72c.

When the anchors 182 and 184 have been installed in the body tissue 72c, as shown in FIG. 16, the guide member 82c and pusher member 112c are withdrawn from the body tissue. At this time, the anchors 182 and 184 have longitudinal central axes which are skewed relative to each other and slope upward (as viewed in FIG. 16) in opposite directions toward the outer side surface of the body tissue 72c. Tensioning of the suture 12c presses the leading end surface 66c on the trailing anchor 182 firmly against the trailing end surface 68c on the leading anchor 184. The two anchors 182 and 184 become wedged together and span the opening in the body tissue 72c to strongly resist pulling out of the anchors 182 and 184 and the suture 12c from the body tissue 72c.

Since the anchors 182 and 184 slope upward (as viewed in FIG. 16) toward the outer side surface of the body tissue 72c and away from each other, pulling on the suture 12c results in the anchors becoming wedged even more firmly in the body tissue. The force applied against the inner side surfaces of the anchors 182 and 184 by pulling on the suture 12c tends to further embed the trailing end portion of the trailing anchor 182 and the leading end portion of the leading anchor 184 in the body tissue. Pulling on the suture 12c tends to center the two anchors 182 and 184 across the opening through which they were inserted into the body tissue 72c.

In the embodiment of the invention illustrated in FIGS. 13–16, the anchors 182 and 184 both have the same general polygonal construction as the anchor 10 of FIG. 1. However, it is contemplated that the anchors 182 and 184 could have a different construction if desired. Thus, the anchor 182 and/or the anchor 184 could have a cylindrical construction. Plural Anchors—Guide and Pusher Members

In the embodiment of the invention illustrated in FIGS. 13–16, the anchors 182 and 184 are randomly oriented relative to the guide member 82c. It is contemplated that it may be desired to orient the anchors 182 and 184 relative to the body tissue 72c before the anchors begin to move into the recess 78. In the embodiment of the invention illustrated in FIG. 17, the guide member is constructed so as to retain the anchors in a selected orientation relative to the guide member as the anchors move axially through the guide member. In addition, the pusher member is constructed so as to apply a concentrated force against a selected portion of the anchor. Since the embodiment of the invention illustrated in FIG. 17 is generally similar to the body of the invention illustrated in FIGS. 13–16 and since the guide members and pusher members are constructed in a manner which is generally similar to the embodiment of the invention illustrated in FIGS. 7–10, similar numerals will be utilized to designate similar components, the suffix letter “d” being associated with the numerals of FIG. 17 to avoid confusion.

In the embodiment of the invention illustrated in FIG. 17, the tubular guide member 82d has a cylindrical outer side surface 88d with a cylindrical inner side surface 92d. In addition, the guide member 82d has a locating rib 142d which orients the anchors 182d and 184d in the guide member 82d. The locating rib 142d extends along the inner side surface 92d of the guide member 82d for the entire length of the guide member.

The locating rib 142d has a flat inwardly facing locating surface 144d. The flat locating surface 144d is disposed in a plane which forms a chord to the cylindrical inner side surface 92d of the guide member 82d. The locating surface 144d has an axial extent which is the same as the axial extent of the guide member 82d.

The locating surface 144d engages the flat outer side surface area 30d on the trailing anchor 182d and the flat outer side surface area 30d on the leading anchor 184d. This enables the locating surface 144d to position the anchors 182d and 184d in a predetermined orientation relative to the guide member 82d. Thus, the corner portions 22d of the anchors 182d and 184d are disposed diametrically across from the locating surface 144d. The locating surface 144d engages the flat outer side surface areas 30d on the anchors 182d and 184d to hold the anchors in a predetermined orientation relative to a longitudinal central axis of the guide member 82d.

A pusher member 112d cooperates with the guide member 82d to apply force against the trailing anchor 182d at the corner portions of the trailing anchor. The pusher member 112d is a cylindrical tubular member having a radially extending slot 150d which extends throughout the length of the pusher member and receives the locating rib 142d. The manner in which the pusher member 112d cooperates with the guide member 82d is the same as previously explained in conjunction with the embodiment of the invention illustrated in FIGS. 7–10. However, the pusher member 112d does not have a tapered leading end portion corresponding to the tapered leading end portion 116a (FIG. 8) of the pusher member 112a. If desired, the pusher member 112d could be provided with a tapered leading end portion.

The pusher member 112d cooperates with the trailing anchor 182d and leading anchor 184d and the guide member 82d to position the anchors 182d and 184d in the same manner as previously explained in conjunction with the embodiment of the invention illustrated in FIGS. 13–16. By using the locating rib 142d, a surgeon can determine the orientation of the anchors in the body tissue 72d by positioning the guide member 82d relative to the body tissue 72d in an orientation corresponding to the desired orientation of the anchors 182 and 184d to the body tissue.

Plural Anchors—Guide Member—Third Embodiment

In the embodiment of the invention illustrated in FIG. 17, the guide member 182d is provided with a locating rib 142d to locate the anchors 182d and 184d relative to the body tissue 72d. In the embodiment of the invention illustrated in FIG. 18, the guide member is provided with a plurality of longitudinally extending grooves which locate the anchors relative to the body tissue. Since the embodiment of the invention illustrated in FIG. 18 is generally similar to the body of the invention illustrated in FIGS. 13–17, similar numerals will be utilized to designate similar components, the suffix letter “e” being associated with the numerals of FIG. 18 to avoid confusion.

The guide member 82e has a cylindrical inner side surface 92e. In accordance with a feature of this embodiment of the invention, the guide member 82e is provided with three spaced-apart and parallel longitudinally extending locating grooves 202, 204, and 206 (FIG. 18). The locating grooves 202, 204, and 206 extend axially throughout the length of the guide member 82e and are spaced equal arcuate distances apart about the cylindrical inner side surface 92e of the guide member 82e. Thus, the locating grooves 202, 204 and 206 are spaced approximately 120° apart.

The corner portions 22e, 24e and 26e on the anchor 182e engage the guide grooves 202, 204, and 206 in the manner

illustrated in FIG. 18. Although only the corner portions **22e**, **24e** and **26e** for the trailing anchor **182e** are shown in FIG. 18, it should be understood that the leading anchor, corresponding to the leading anchor **184** of FIG. 13, has corner portions which engage the guide grooves **202**, **204**, and **206** in the same manner as do the corner portions of the trailing anchor.

The pusher member has not been shown in FIG. 18, it is contemplated that a cylindrical pusher member, similar to the pusher member **112** of FIGS. 8 and 9 may be used to apply force against the trailing end surface **68e** of the anchor **182e** (FIG. 18).

Plural Anchors—Second Embodiment

In the embodiment of the invention illustrated in FIGS. 13–16, the anchors **182** and **184** are formed separately from each other. This requires a surgeon to properly align and thread the anchors on the suture **12c** in the manner illustrated in FIG. 13. In the embodiment of the invention illustrated in FIGS. 19 and 20, a connector portion is provided to interconnect the two anchors. The connector portions retains the anchors in the proper orientation relative to each other and facilitate threading of the suture through the two anchors. Since the embodiment of the invention illustrated in FIGS. 19 and 20 is generally similar to the embodiment of the invention illustrated in FIGS. 13–16, similar numerals will be utilized to designate similar components, the suffix letter “f” being used in conjunction with the numerals of FIGS. 19 and 20 to avoid confusion.

An anchor **182f** (FIG. 19) has the same construction as the anchor **182** of FIGS. 13–16. An anchor **184f** has the same construction as the anchor **184** of FIGS. 13–16. In accordance with a feature of this embodiment of the invention, the anchors **182f** and **184f** are interconnected by a connector **220** which extends between the two anchors **182f** and **184f**. The connector **220** has a length which is coextensive with the width of side walls **58f** of the anchors **182f** and **184f**.

The anchors **182f** and **184f** have side walls **58f** with flat outer side surface areas **30f** which are disposed in a common plane. In addition, the anchors **182f** and **184f** have outer corner portions **22f** which are axially aligned with each other. The outer side surface areas **30f** on the side walls **58f** of the anchors **182f** and **184f** are maintained in alignment with each other by the connector **220**. In addition, the connector **220** maintains the outer corner portions **24f** on the anchors **182f** and **184f** in alignment with each other.

Since the two anchors **182f** and **184f** are interconnected by the connector **220**, the tapered leading end portion **186f** of the trailing anchor **182f** always faces toward the trailing end surface **68f** of the leading anchor **184f**. Therefore, when a suture **12f** (FIG. 20) is threaded through the anchors **182f** and **184f**, the anchors are always in the proper orientation relative to each other.

When the anchors **182f** and **184f** are installed in body tissue, in the manner illustrated in FIGS. 13–16 for the anchors **182** and **184**, the connector **220** is deformed to enable the leading anchor **184f** to move from the orientation shown in FIG. 19 to the orientation shown in FIG. 20 relative to the anchor **182f**. Thus, when the anchors **182f** and **184f** have been moved to their installed positions relative to each other, in the manner illustrated in FIG. 20, the connector **220** is bent so that the leading end surface **66f** on the anchor **182f** and the trailing end surface **68f** on the anchor **184f** are disposed in abutting engagement.

The connector **220** is a web which extends along the leading end portion of the outer side surface **30f** in the side wall **58f** of the anchor **182f** and along a trailing portion of the outer side surface **30f** of the side wall **58f** of the anchor **184f**.

The relatively thin web forming the connector **220** is integrally formed with the two anchors **182f** and **184f**. Thus, the two anchors **182f** and **184f** are formed as one piece having the configuration of an equilateral triangular prism. The leading end surface **66f** on the anchor **182f** and the trailing end surface **68f** on the anchor **184f** are formed by making a notch in the one piece prism. The notch does not extend completely through the side walls **58d** so that the thin web of the connector **220** remains to interconnect the two anchors **182f** and **184f**.

Although it is preferred to form the anchors **182f** and **184f** from a single piece of material with a thin web or connector **220** between the two anchors, it is contemplated that the anchors **182f** and **184f** could be formed from two separate pieces of material and interconnected by a separate connector **220**. If this was done, the connector **220** could be formed of a material which is different than the material of the anchors **182f** and **184f**. For example, the connector **220** could be formed of a suitable polymeric material and bonded to the leading end surface **66f** of the anchor **182f** and to the trailing end surface **68f** of the anchor **184f**. If this was done, the polymeric material could be ruptured or broken as the connector **220** is deformed during installation of the anchors **182f** and **184f** and movement of the anchors to the orientation shown in FIG. 20.

It is also contemplated that the connector **220** could be formed by a plurality of relatively thin elements which are disposed at spaced apart locations along the leading end of the flat outer side surface **30f** of the side wall **58f** of the anchor **182f** and the trailing end of the flat outer side surface **30f** of the side wall **58f** of the leading anchor **184f**. The thin spaced apart connector portions could be integrally formed with the anchors **182f** and **184f** or could be formed of a suitable connector material which extends between the anchors and used to interconnect them, such as spots or small bodies of adhesive.

Conclusion

In view of the foregoing description, it is apparent that the present invention provides a new and improved method and apparatus for securing a suture **12** in body tissue. An improved suture anchor **10** has a polygonal cross-sectional configuration with an outer side **14** which is formed by a plurality of flat side surface areas **28**, **30**, and **32** which are interconnected by outer corner portions **22**, **24**, and **26**. The anchor **10** has a passage **18** formed by a plurality of flat inner side surface areas **48**, **50**, and **52** which are interconnected by a plurality of inner corner portions **40**, **42** and **44**. The suture **12** is engageable with one of the inner corner portions **40**, **42** or **44** to urge an outer corner portion **22**, **24**, or **26** of the anchor **10** into engagement with body tissue **72**. A groove **162** may be provided in the end and/or outer side of the anchor to receive the suture.

A plurality of anchors **182** and **184** having the configuration of the anchor **10** or a different configuration may be used to anchor a suture. When a plurality of anchors are used, the suture **12** is inserted through each of the anchors and the anchors are sequentially moved into the body tissue. As a leading anchor **184** is moved into the body tissue, the suture **12** is tensioned to move a corner portion **22** on the leading anchor into engagement with the body tissue. A connector **220** may be provided between each anchor.

Having described the invention, the following is claimed:

1. A method of securing body tissue, said method comprises the steps of providing a plurality of anchors with a suture extending between the anchors, moving the plurality of anchors into body tissue with the suture extending between the anchors, and transmitting force between the

23

plurality of anchors through the suture after the plurality of anchors have been moved into the body tissue, said step of transmitting force between the plurality of anchors through the suture includes tensioning a portion of the suture extending between the plurality of anchors.

2. A method as set forth in claim 1 wherein said step of moving the plurality of anchors into body tissue includes engaging a first one of the anchors of the plurality of anchors with a guide member and moving the first one of the anchors along the guide member into the body tissue, and engaging a second one of the anchors of the plurality of anchors with the guide member and moving the second one of the anchors along the guide member into the body tissue, said step of moving the second one of the anchors along the guide member is performed with the suture extending between the first and second anchors.

3. A method as set forth in claim 1 wherein said step of providing a plurality of anchors with a suture extending between the anchors includes providing a first anchor with a first passage extending through the first anchor and providing a second anchor with a second passage extending through the second anchor, said step of moving the plurality of anchors into body tissue is performed with the suture extending through the first and second passages in the first and second anchors, said step of transmitting force between the plurality of anchors through the suture includes pressing the suture against the passage extending through the first anchor and pressing the suture against the passage extending through the second anchor after the plurality of anchors have been moved into the body tissue.

4. A method as set forth in claim 3 wherein the passage extending through the first anchor has a first corner portion and the passage extending through the second anchor has a second corner portion, said step of pressing the suture against the passage through the first anchor includes pressing the suture against the corner portion of the passage through the first anchor, said step of pressing the suture against the passage through the second anchor includes pressing the suture against the corner portion of the passage through the second anchor.

5. A method as set forth in claim 1 wherein said step of providing a plurality of anchors with a suture extending

24

between the anchors includes providing a first anchor with a first passage extending between axially opposite end portions of the first anchor and providing a second anchor with a second passage extending between axially opposite end portions of the second anchor, said step of moving the plurality of anchors into body tissue is performed with the suture extending through the first and second passages into the first and second anchors, said step of transmitting force between the plurality of anchors includes pressing the suture against the passage in the first anchor and pressing the suture against the passage in the second anchor after the plurality of anchors have been moved into the body tissue.

6. A method as set forth in claim 5 wherein the passage extending between axially opposite end portions of the first anchor has a first corner portion and the passage extending between axially opposite end portions of the second anchor has a second corner portion, said step of pressing the suture against the passage in the first anchor includes pressing the suture against the corner portion of the passage in the first anchor, said step of pressing the suture against the passage in the second anchor includes pressing the suture against the corner portion of the passage in the second anchor.

7. A method as set forth in claim 1 further including the step of rotating a first anchor of the plurality of anchors to change the orientation of the first anchor relative to the body tissue after moving the first anchor into the body tissue, and rotating a second anchor of the plurality of anchors to change the orientation of the second anchor relative to the body tissue after moving the second anchor into the body tissue.

8. A method of securing body tissue, said method comprises the steps of moving an anchor into body tissue with a suture extending through a passage in the anchor, tensioning the suture while the anchor is disposed in the body tissue, and deforming the anchor under the influence of force transmitted through the suture while tensioning the suture.

9. A method as set forth in claim 8 wherein said step of deforming the anchor includes bending the anchor under the influence of force transmitted to the anchor from the suture.
